# CS 229 Homework

Tyler Neylon

345.2016

These are solutions to the most recent problems posted for Stanford's CS 229 course, as of June 2016. I'm not sure if this course re-uses old problems, but please don't copy the answers if so. This document is also available as a pdf.

## 1 Problem set 1

### 1.1 Logistic regression

#### 1.1.1 Part (a)

The problem is to compute the Hessian matrix $H$ for the function

$$J(\theta) = -\frac{1}{m}\sum_{i=1}^{m} \log(g(y^{(i)}x^{(i)})),$$

where $g(z)$ is the logistic function, and to show that $H$ is positive semi-definite; specifically, that $z^T H z \geq 0$ for any vector $z$.

We'll use the fact that $g'(z) = g(z)(1 - g(z))$. We'll also note that since all relevant operations are linear, it will suffice to ignore the summation over $i$ in the definition of $J$. I'll use the notation $\partial_j$ for $\frac{\partial}{\partial \theta_j}$, and introduce $t$ for $y\theta^T x$. Then

$$-\partial_j(mJ) = \frac{g(t)(1-g(t))}{g(t)} x_j y = x_j y(1 - g(t)).$$

Next

$$-\partial_k \partial_j (mJ) = x_j y\big( - g(t)(1-g(t))\big) x_k y,$$

so that

$$\partial_{jk}(mJ) = x_j x_k y^2 \alpha,$$

where $\alpha = g(t)(1 - g(t)) > 0$.

Thus we can use repeated-index summation notation to arrive at

$$z^T H z = z_i h_{ij} z_j = (\alpha y^2)(z_i x_i x_j z_j) = (\alpha y^2)(x^T z)^2 \geq 0.$$

This completes this part of the problem.

### 1.1.2 Part (b)

Here is a matlab script to solve this part of the problem:

```
% problem1_1b.m
%
% Run Newton's method on a given cost function for a logistic
% regression setup.
%

printf('Running problem1_1b.m\n');

% Be able to compute J.
function val = J(Z, theta)
  [m, _] = size(Z);
  g      = 1 ./ (1 + exp(Z * theta));
  val    = -sum(log(g)) / m;
end

% Setup.
X      = load('logistic_x.txt');
[m, n] = size(X);
X      = [ones(m, 1) X];
Y      = load('logistic_y.txt');
Z      = diag(Y) * X;

% Initialize the parameters to learn.
old_theta =  ones(n + 1, 1);
theta     = zeros(n + 1, 1);
i         = 1;  % i = iteration number.

% Perform Newton's method.
while norm(old_theta - theta) > 1e-5
  printf('J = %g\n', J(Z, theta));
```

```
  printf('theta:\n');
  disp(theta);
  printf('Running iteration %d\n', i);

  g         = 1 ./ (1 + exp(Z * theta));
  f         = (1 - g);
  alpha     = f .* g;
  A         = diag(alpha);
  H         = Z' * A * Z / m;
  nabla     = Z' * f / m;
  old_theta = theta;
  theta     = theta - inv(H) *  nabla;

  i++;
end

% Show and save output.
printf('Final theta:\n');
disp(theta);
save('theta.mat', 'theta');
```

Because I have copious free time, I also wrote a Python version. Also because I'm learning numpy and would prefer to consistently use a language that I know can produce decent-looking graphs. Here is the Python script:

```
#!/usr/bin/env python

import numpy as np
from numpy import linalg as la

# Define the J function.
def J(Z, theta):
  m, _ = Z.shape
  g    = 1 / (1 + np.exp(Z.dot(theta)))
  return -sum(np.log(g)) / m

# Load data.
X    = np.loadtxt('logistic_x.txt')
m, n = X.shape
X    = np.insert(X, 0, 1, axis=1)  # Prefix an all-1 column.
Y    = np.loadtxt('logistic_y.txt')
Z    = np.diag(Y).dot(X);

# Initialize the learning parameters.
old_theta = np.ones((n + 1,))
theta     = np.zeros((n + 1,))
```

```
i         = 1

# Perform Newton's method.
while np.linalg.norm(old_theta - theta) > 1e-5:

  # Print progress.
  print('J = {}'.format(J(Z, theta)))
  print('theta = {}'.format(theta))
  print('Running iteration {}'.format(i))

  # Update theta.
  g         = 1 / (1 + np.exp(Z.dot(theta)))
  f         = 1 - g
  alpha     = (f * g).flatten()
  H         = (Z.T * alpha).dot(Z) / m
  nabla     = Z.T.dot(f) / m
  old_theta = theta
  theta     = theta - la.inv(H).dot(nabla)

  # Update i = the iteration counter.
  i += 1

# Print and save the final value.
print('Final theta = {}'.format(theta))
np.savetxt('theta.txt', theta)
```

The final value of $\theta$ that I arrived at is

$$\theta = (2.62051, -0.76037, -1.17195).$$

The first value $\theta_0$ represents the constant term, so that the final model is given by

$$y = g(2.62 - 0.76x_1 - 1.17x_2).$$

#### 1.1.3 Part (c)

### 1.2 Poisson regression and the exponential family

#### 1.2.1 Part (a)

Write the Poisson distribution as an exponential family:

$$p(y; \eta) = b(y) \exp\left(\eta^T T(y) - a(\eta)\right),$$

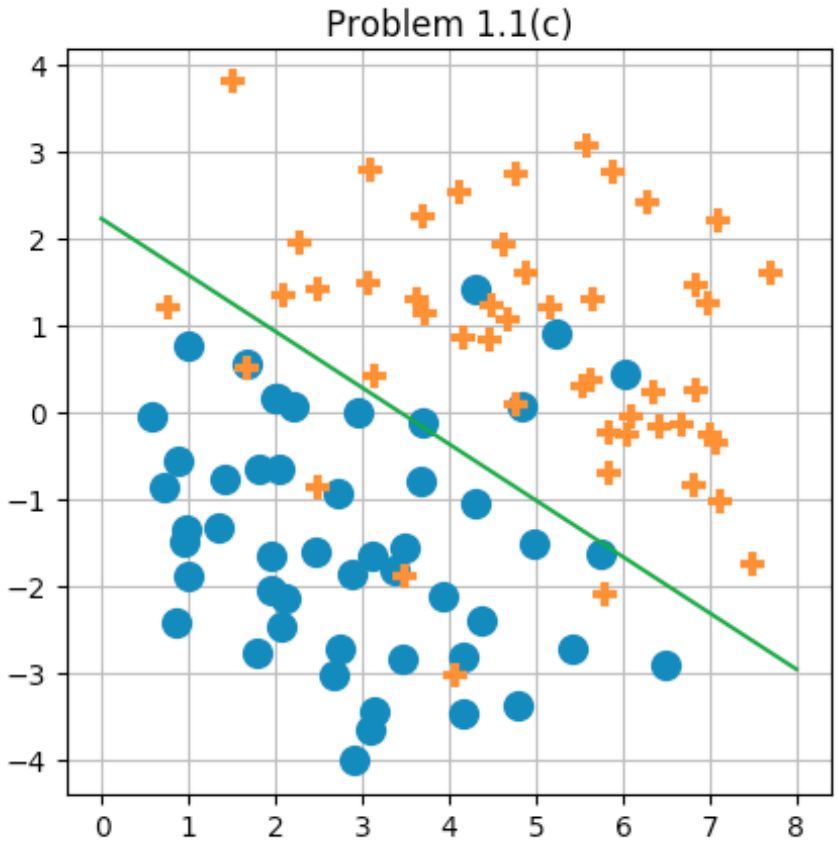

Figure 1: The data points given for problem 1.1 along with the decision boundary learned by logistic regression as executed by Newton's method.

where

$$p(y;\lambda) = \frac{e^{-\lambda}\lambda^y}{y!}.$$

This can be done via

$$\begin{aligned} \eta &= \log(\lambda), \\ a(\eta) &= e^{\eta} = \lambda, \\ b(y) &= 1/y!, \text{ and} \\ T(y) &= y. \end{aligned}$$

### 1.2.2 Part (b)

As is usual with generalized linear models, we'll let $\eta = \theta^T x$. The canonical response function is then given by

$$g(\eta) = E[y;\eta] = \lambda = e^{\eta} = e^{\theta^T x}.$$

### 1.2.3 Part (c)

Based on the last part, I'll define the hypothesis function $h$ via $h(x) = e^{\theta^T x}$.

For a single data point $(x, y)$, let $\ell(\theta) = \log(p(y|x)) = \log(\frac{1}{y!}) + (y\theta^T x - e^{\theta^T x})$. Then

$$\frac{\partial}{\partial \theta_j}\ell(\theta) = yx_j - x_j e^{\theta^T x} = x_j(y - e^{\theta^T x}).$$

So stochastic gradient ascent for a single point $(x, y)$ would use the update rule

$$\theta := \theta + \alpha x(y - h(x)).$$
